Resumo	Studies have reported that flavonoids inhibit xanthine oxidase (XO) activity; however, poor solubility and stability in lipophilic media limit their bioavailability and applications. This study evaluated the kinetic parameters of XO inhibition and partition coefficients of flavonoid esters biosynthesised from hesperidin, naringin, and rutin <i>via</i> enzymatic acylation with hexanoic, octanoic, decanoic, lauric, and oleic acids catalysed by <i>Candida antarctica</i> lipase B (CALB). Quantitative determination by ultra-high performance liquid chromatography–mass spectrometry (UHPLC–MS) showed higher conversion yields (%) for naringin and rutin esters using acyl donors with 8C and 10C. Rutin decanoate had higher partition coefficients (0.95), and naringin octanoate and naringin decanoate showed greater inhibitory effects on XO (IC_{50} of 110.35 and 117.51 μ M, respectively). Kinetic analysis showed significant differences ($p < .05$) between the flavonoids before and after acylation regarding K_m values, whereas the values for V_{max} were the same, implying the competitive nature of XO inhibition.
